RQ2: entropy separates accurate from inaccurate instances in 3 of 8 models
Bars would separate if entropy tracked accuracy. They do for BERT-base, BioBERT, PubMedBERT; they do not for the remaining 5.
CADEC: n = 37,696 analysed rows, 37,695 drawn (1 have no defined entropy), 8 models. Starred values clear the pre-registered 0.30.
SIGNS DIFFER BY CONSTRUCTION. rho is Spearman(entropy, ERROR), as reported in the manuscript table, so higher entropy with more error is POSITIVE. r(rb) contrasts the correct stratum against the incorrect one, so the same relationship is NEGATIVE. Both describe entropy rising with error.
Split: the 25th and 75th percentile cut was attempted and is degenerate, q25 = q75 = 0 for 4 of the 8 CADEC models, so the split drawn is instances with at least one correct variant against instances with none.
